<http://microservices.io>

Presentation goal

Show how Event Sourcing and
Command Query Responsibility Segregation
(CQRS)
are a great way to implement microservices

About Chris

@crichtson

About Chris

- Founder of a startup that's creating a platform for developing event-driven microservices: <http://eventuate.io/>
- Consultant helping organizations improve how they architect and deploy applications using cloud, micro services, polyglot applications, NoSQL, ...
- Creator of <http://microservices.io>

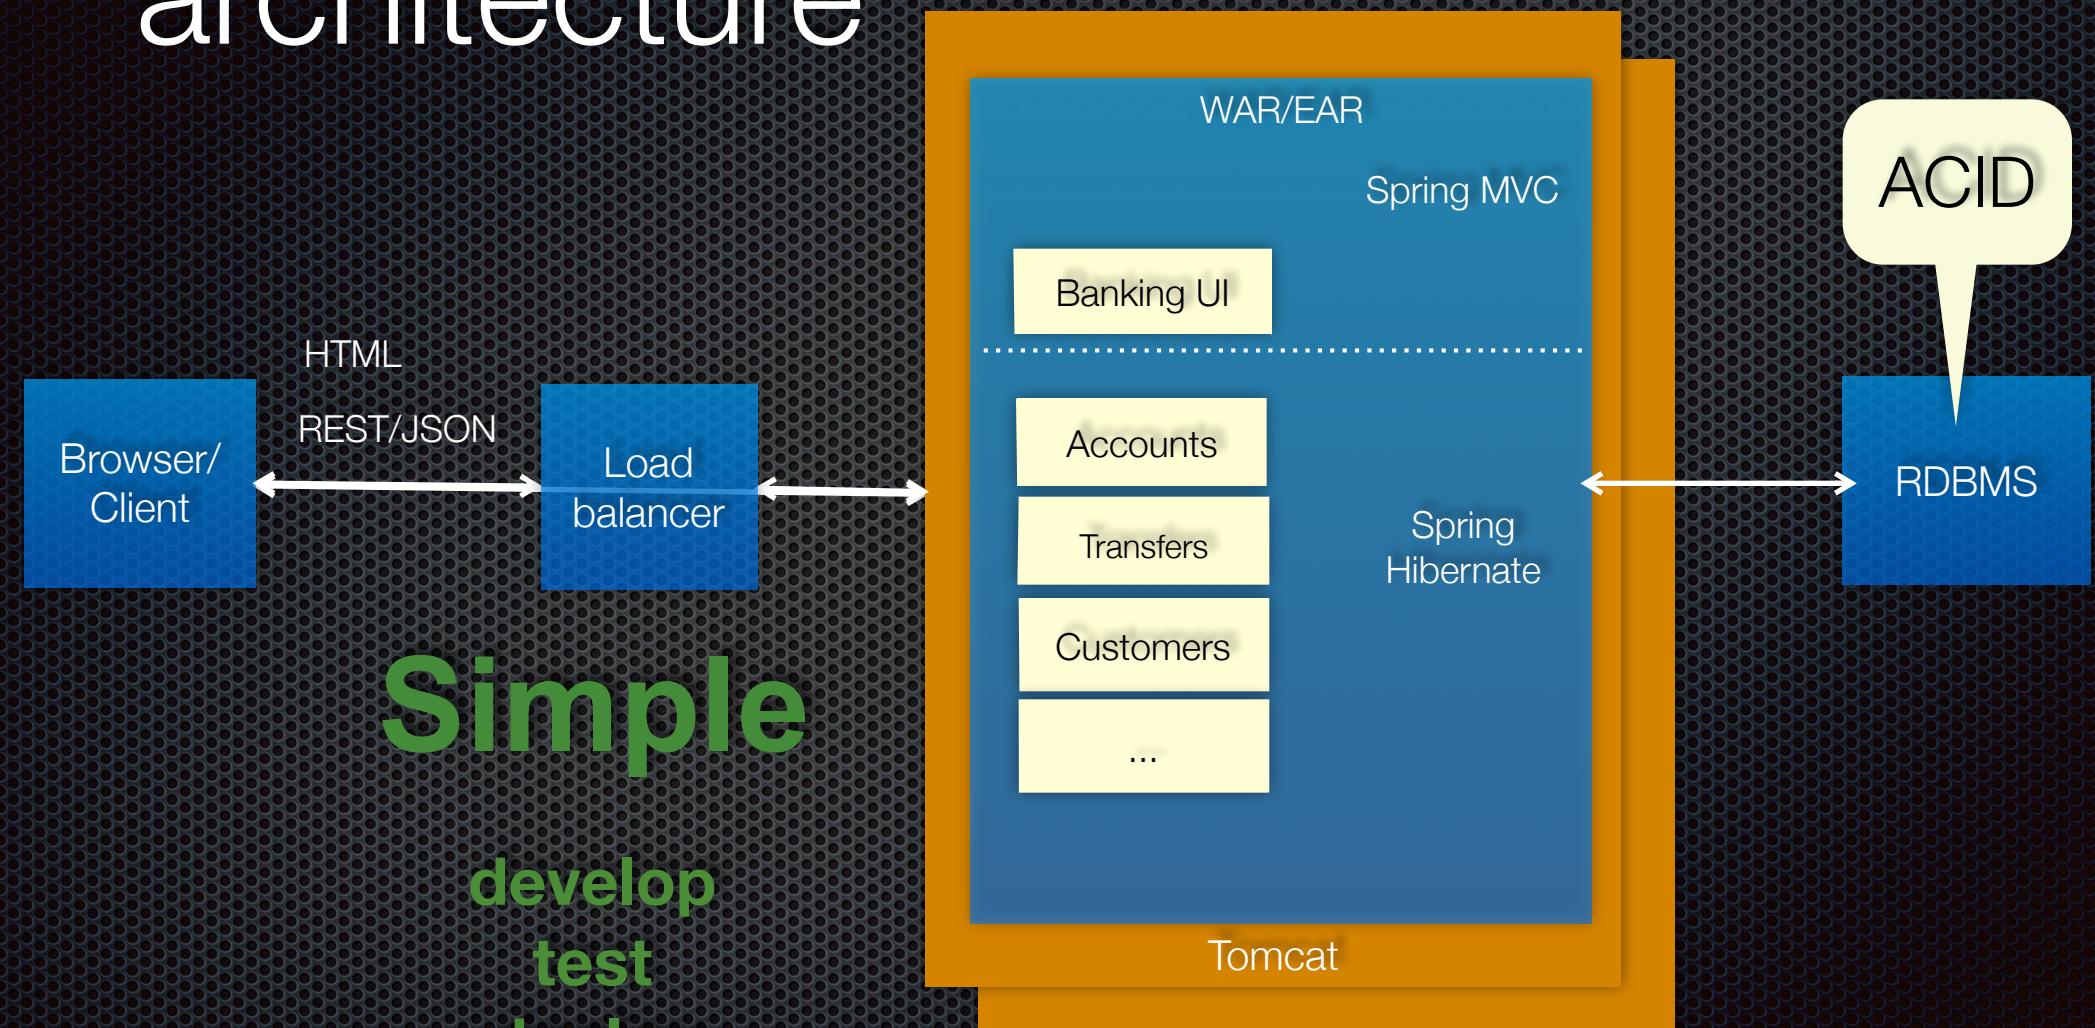

For more information

- <http://microservices.io>
- <http://github.com/cer/microservices-examples>
- <https://github.com/cer/event-sourcing-examples>
- <http://plainoldobjects.com/>
- <https://twitter.com/crichardson>

Agenda

- Why build event-driven microservices?
- Overview of event sourcing
- Designing microservices with event sourcing
- Implementing queries in an event sourced application

Traditional monolithic architecture

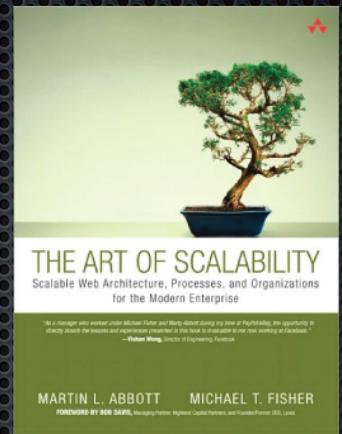

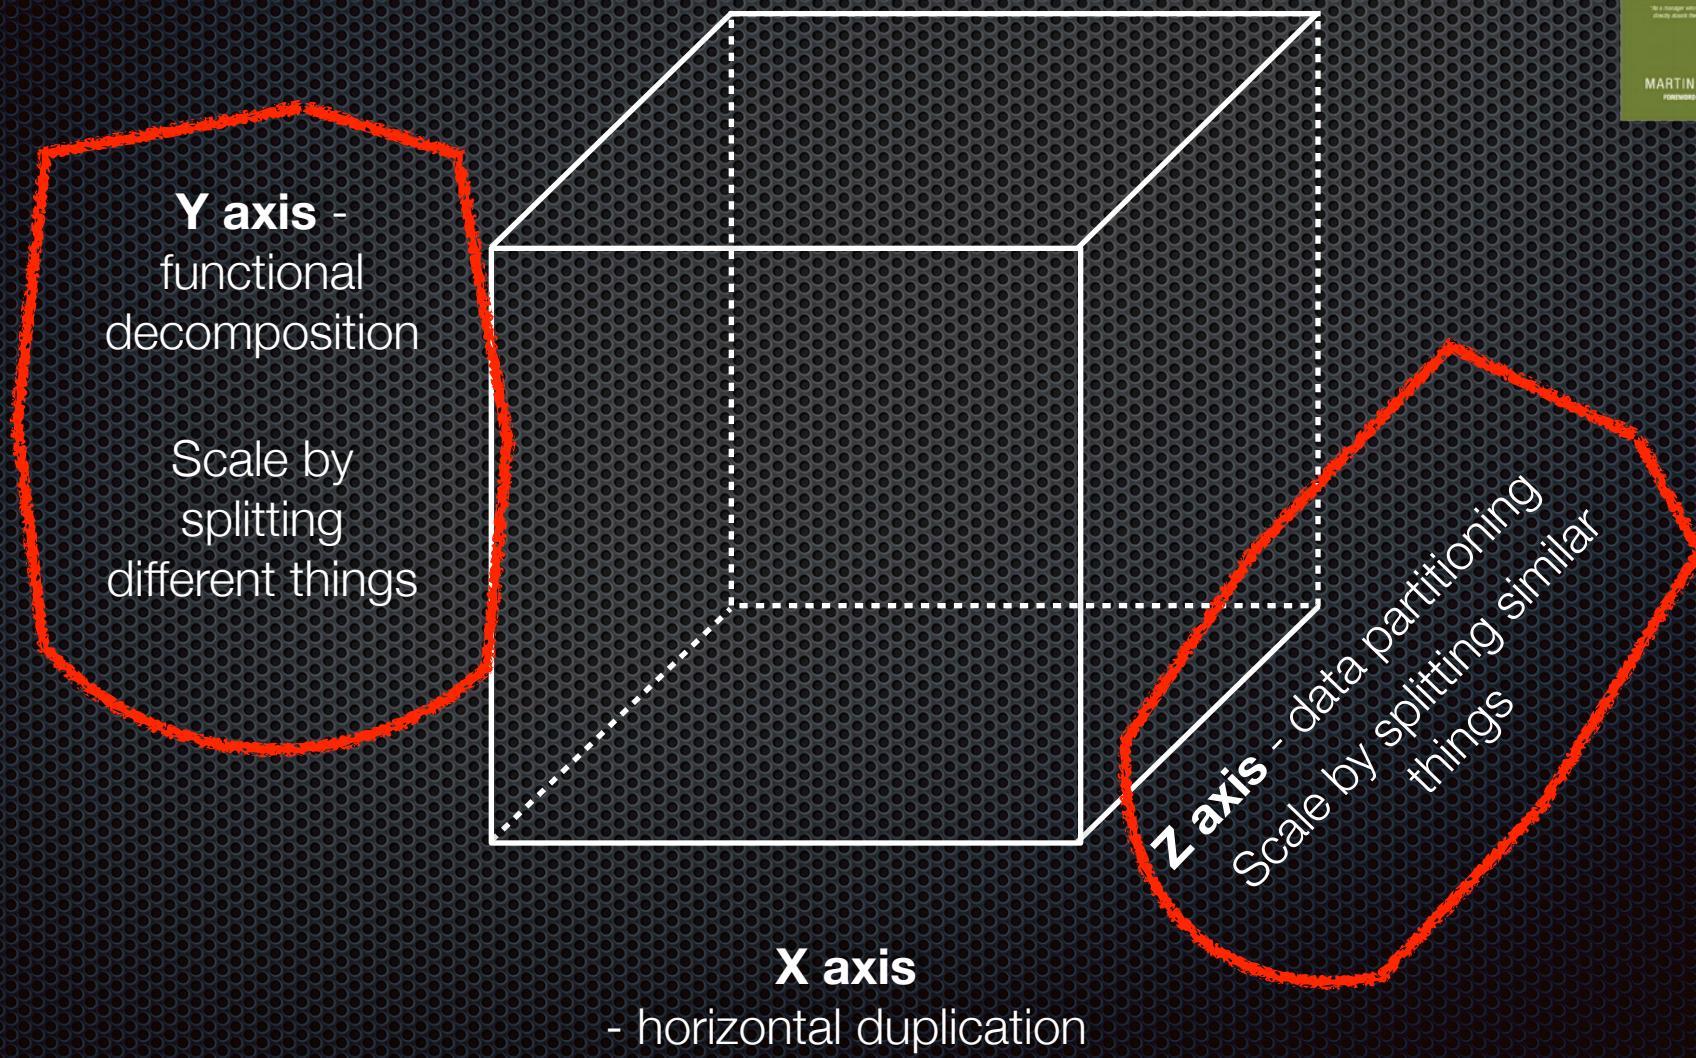

Simple
develop
test
deploy
scale

But large and/or complex
monolithic applications

=

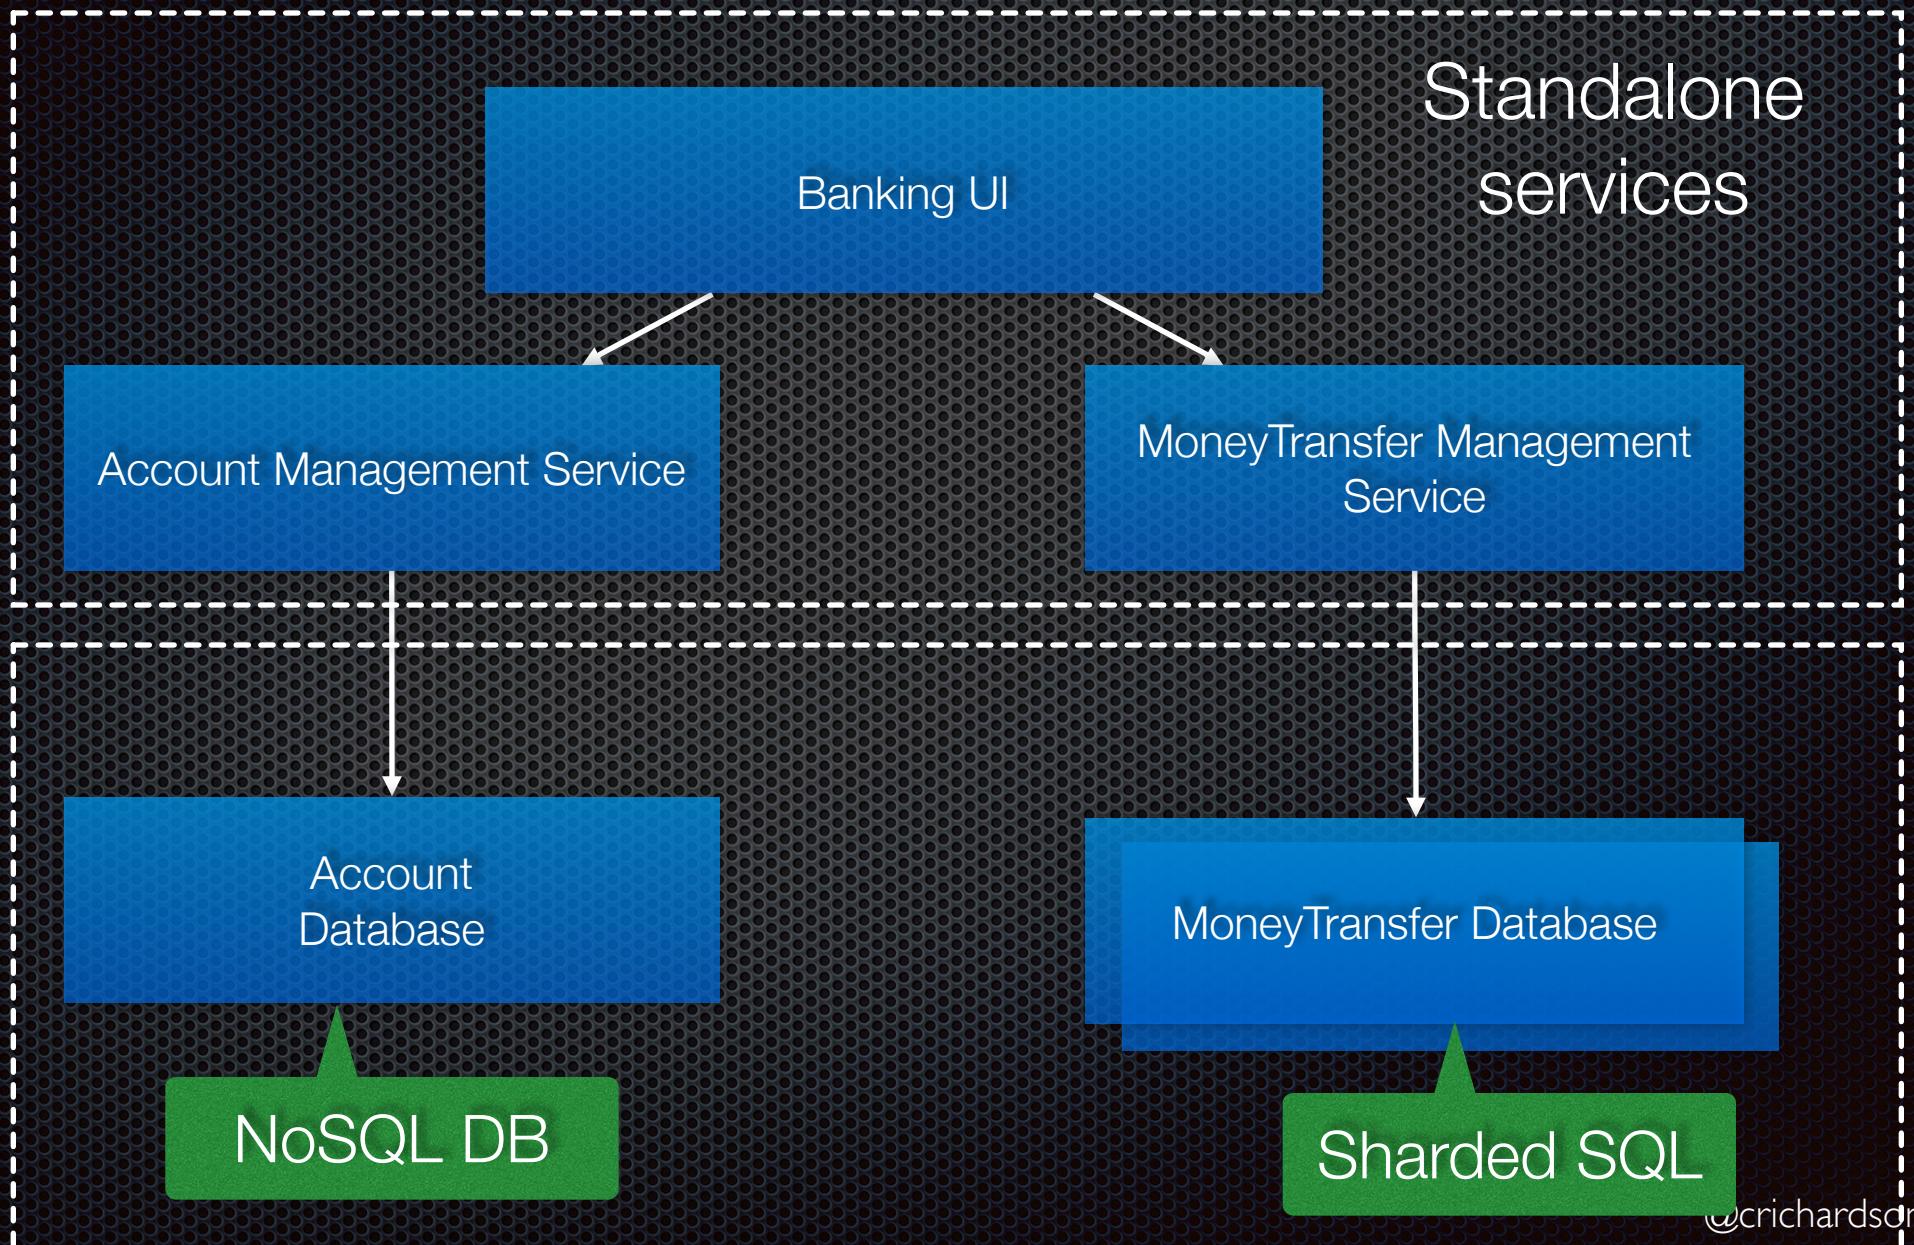

Trouble!

Apply the scale cube

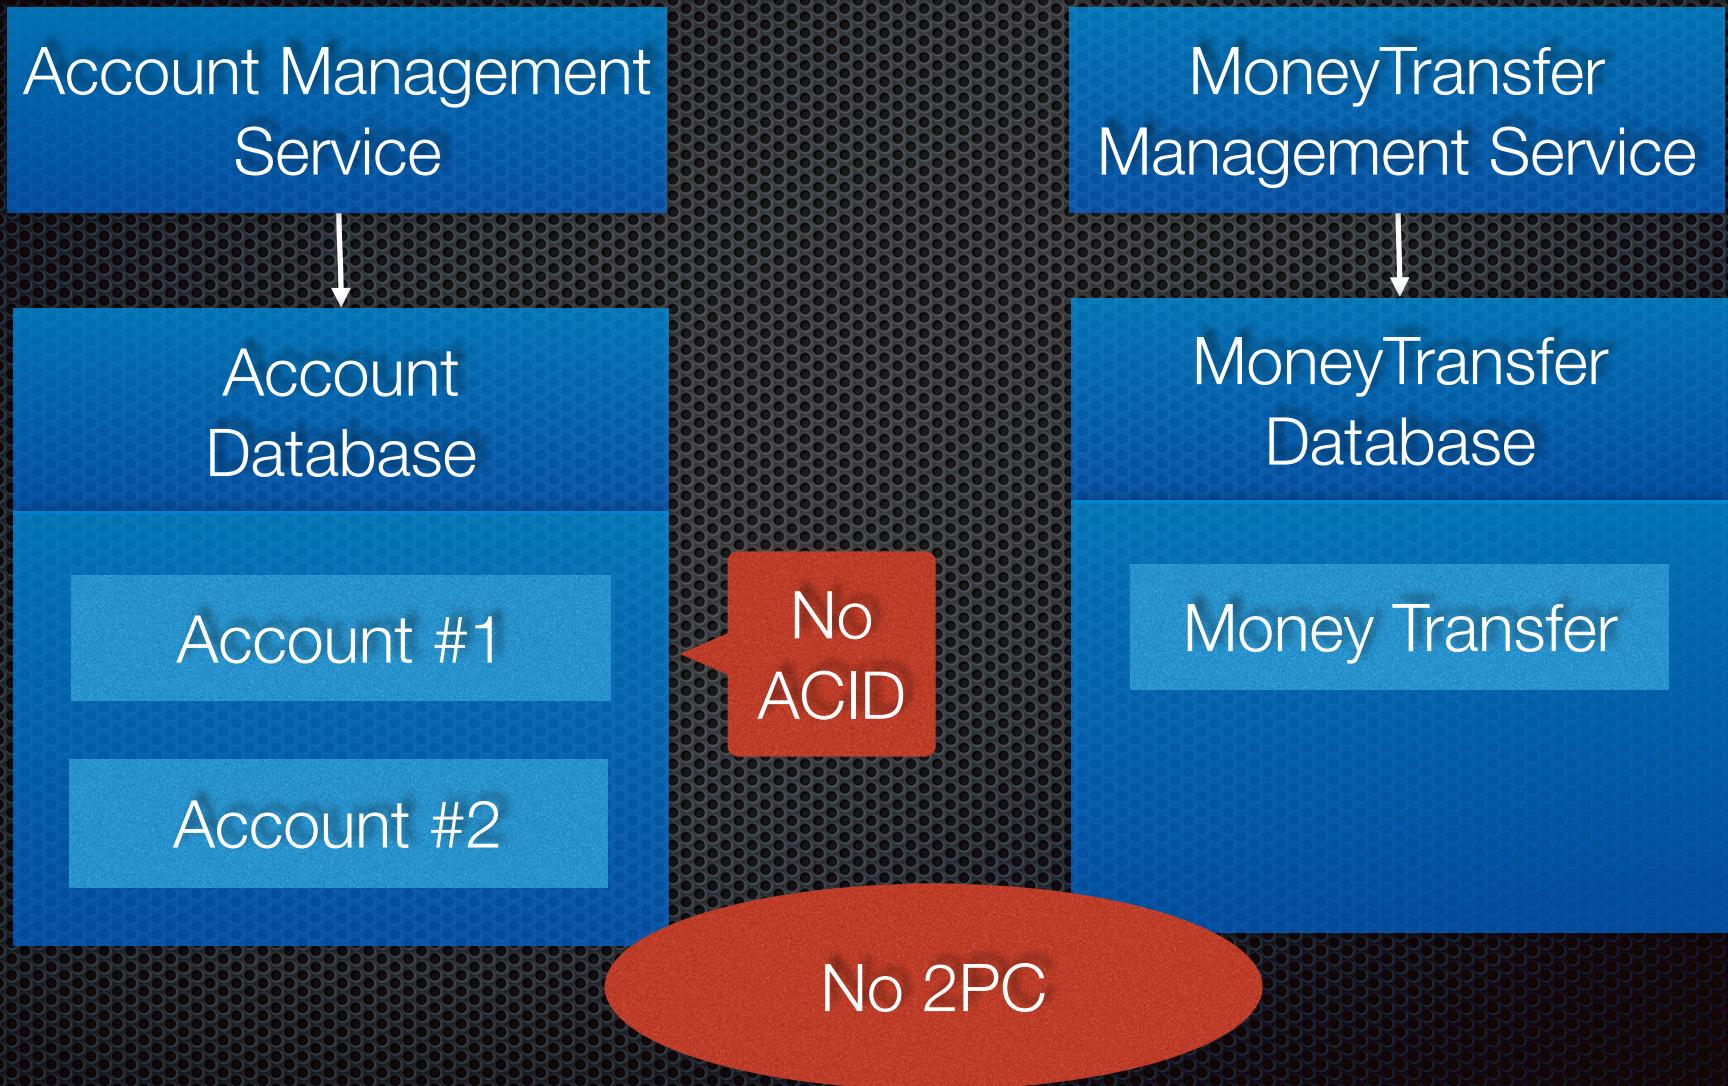

@crichardson

Today: use a microservice, polyglot architecture

But this results in distributed
data management problems

Example: Money transfer

Use an event-driven

- Services publish events when state changes
- Services subscribe to events and update their state
 - Maintain eventual consistency across multiple aggregates (in multiple datastores)
 - Synchronize replicated data

Eventually consistent money transfer

transferMoney()

MoneyTransferService

MoneyTransfer
fromAccountId = 101
toAccountId = 202
amount = 55
state = COMPLETED

AccountService

Account
id = 101
balance = 195

Account
id = 202
balance = 180

Subscribes to:

AccountDebitedEvent
AccountCreditedEvent

publishes:

MoneyTransferCreatedEvent
DebitRecordedEvent

Subscribes to:

MoneyTransferCreatedEvent
DebitRecordedEvent

Publishes:

AccountDebitedEvent
AccountCreditedEvent

Message Bus

How to
atomically
update state
and
publish an event

Update and publish using 2PC

- Guaranteed atomicity **BUT**
- Need a distributed transaction manager
- Database and message broker must support 2PC
- Impacts reliability
- Not fashionable
- 2PC is best avoided

Use data store as message queue

- ✖ Use datastore as a message queue
 - ✖ Txn #1: Update database: new entity state & event
 - ✖ Txn #2: Consume event
 - ✖ Txn #3: Mark event as consumed
- ✖ Eventually consistent mechanism (used by eBay)
- ✖ See BASE: An Acid Alternative, <http://bit.ly/ebaybase>
- ✖ **BUT**
- ✖ Tangled business logic and event publishing code
- ✖ Difficult to implement when using a NoSQL database :-(

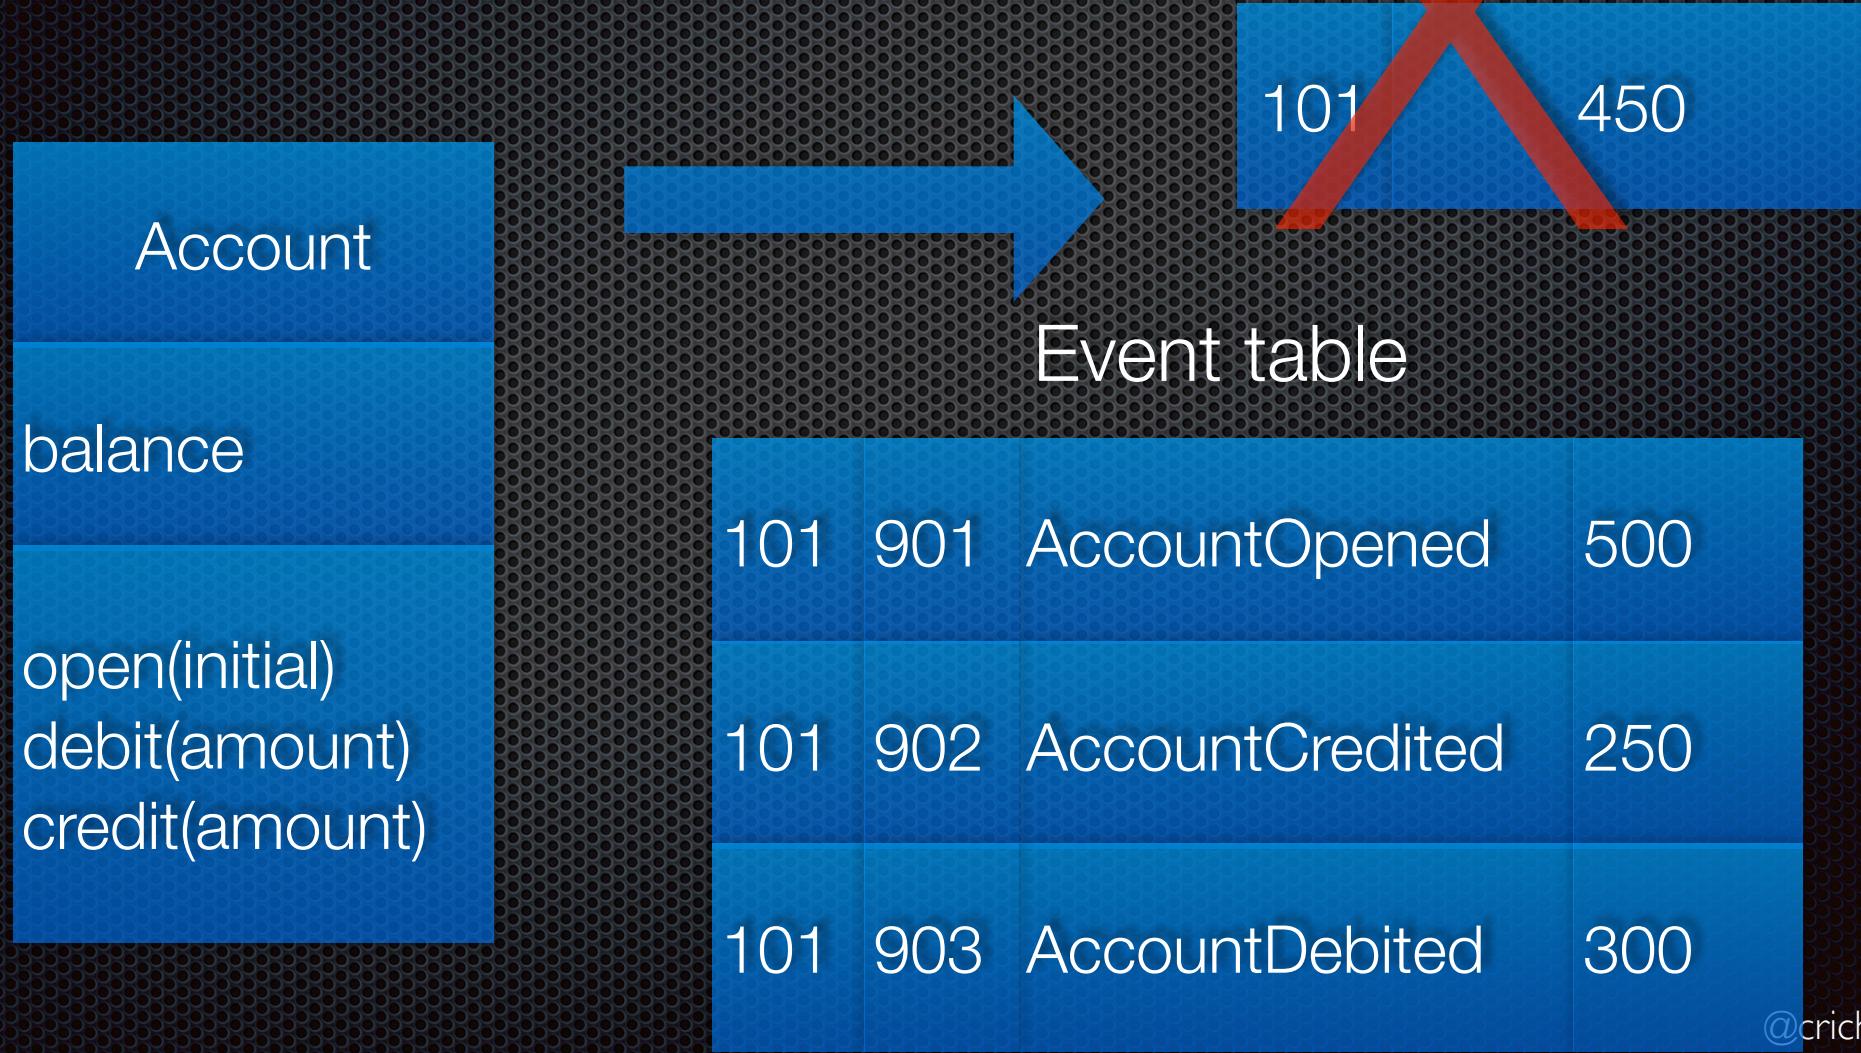

Agenda

- Why build event-driven microservices?
- Overview of event sourcing
- Designing microservices with event sourcing
- Implementing queries in an event sourced application

Event sourcing

- For each aggregate in your domain model:
 - Identify (state-changing) domain events
 - Define Event classes
- For example,
 - Account: AccountOpenedEvent, AccountDebitedEvent, AccountCreditedEvent
 - ShoppingCart: ItemAddedEvent, ItemRemovedEvent, OrderPlacedEvent

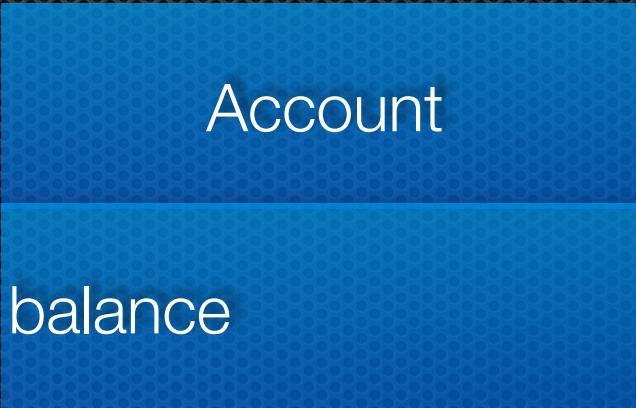

Persists events NOT current state

Replay events to recreate state

Events

AccountOpenedEvent(balance)
AccountDebitedEvent(amount)
AccountCreditedEvent(amount)

Two actions that must be atomic

Before: update state + publish events

Now: persist (and publish) events

Single action that can be done atomically

Request handling in an event-sourced application

Microservice A

`pastEvents = findEvents(entityId)`

`new()`

`applyEvents(pastEvents)`

`newEvents = processCmd(SomeCmd)`

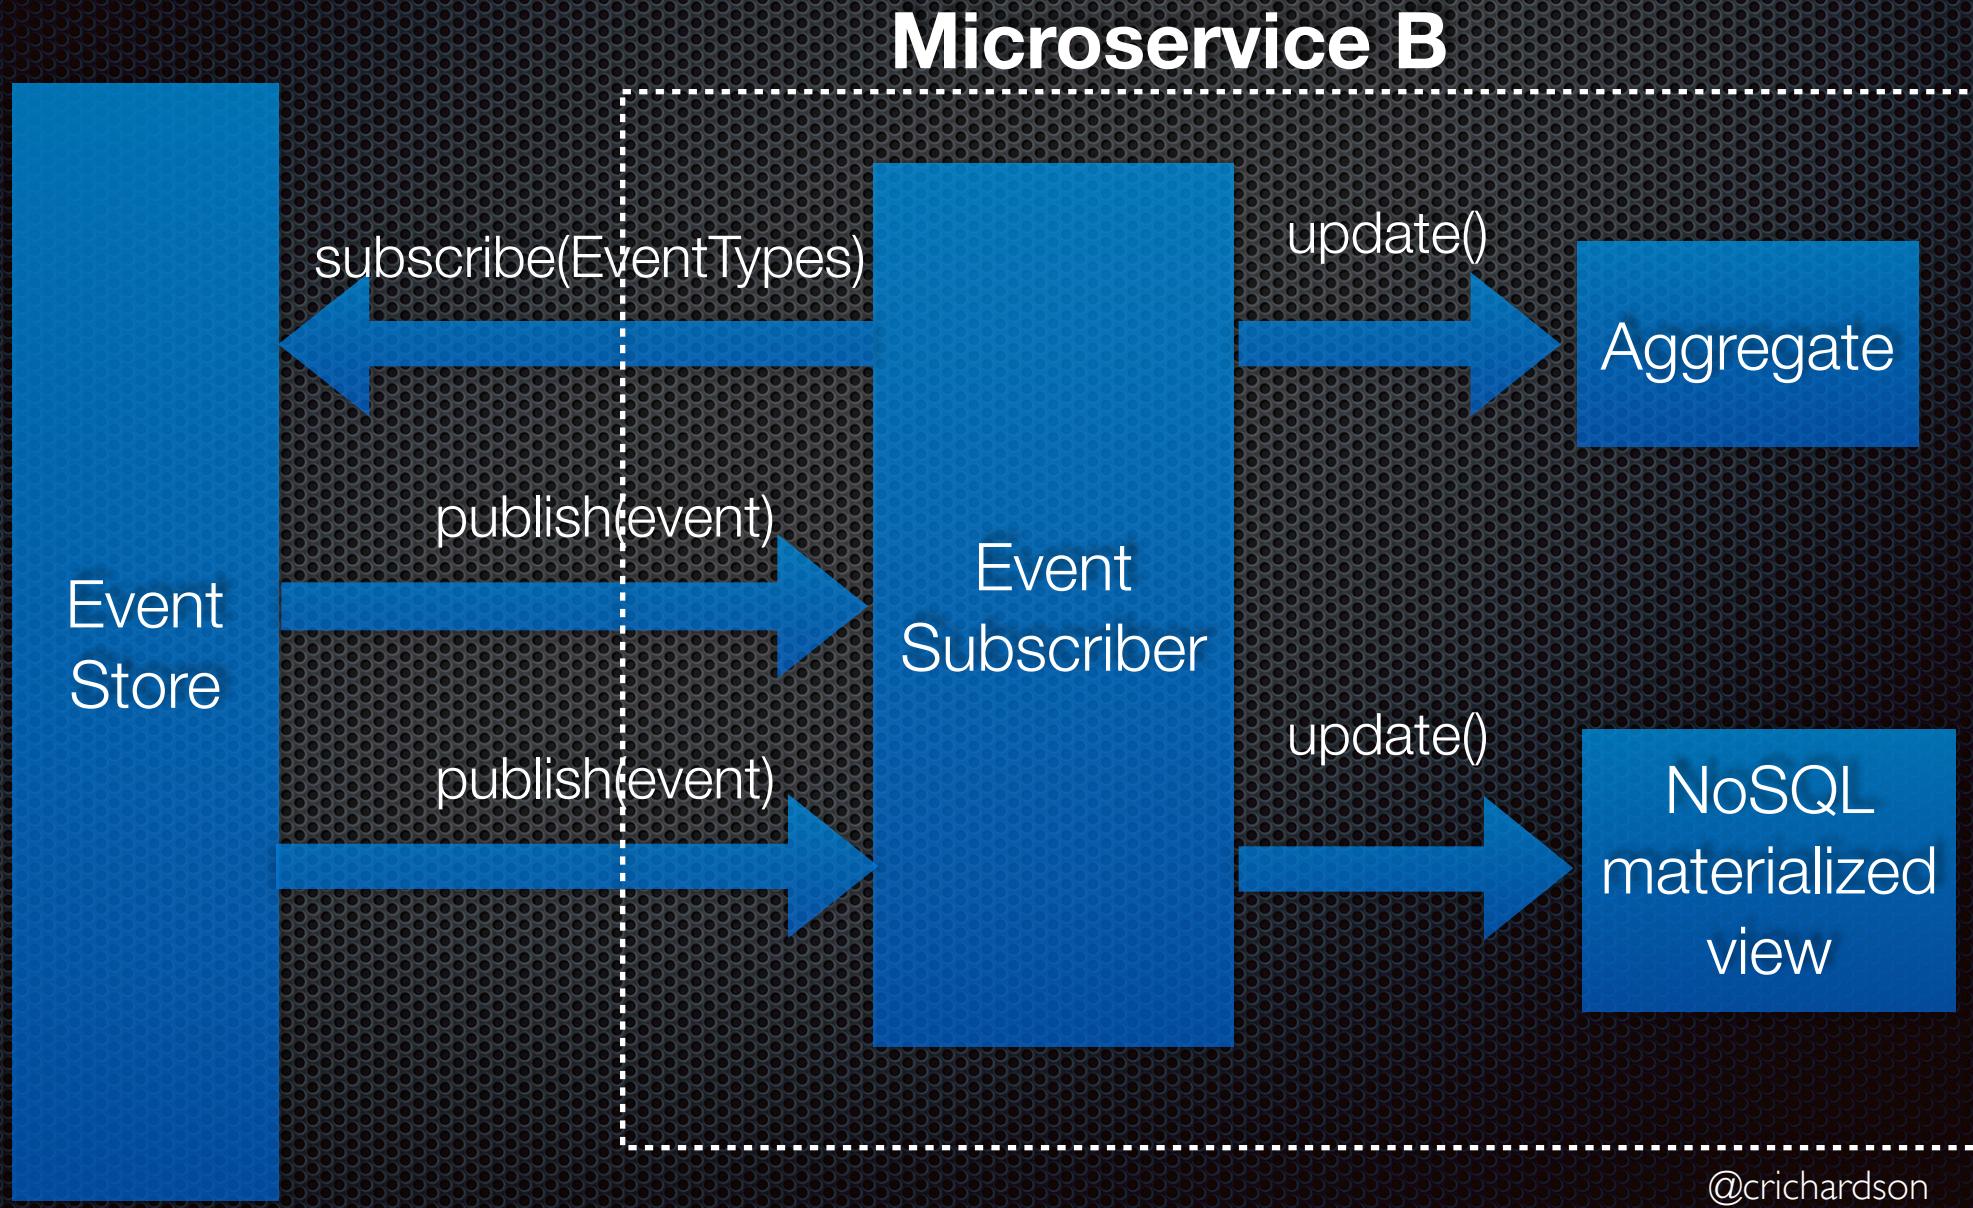

HTTP
Handler

Account

Event
Store

`saveEvents(newEvents)`

Event Store publishes events - consumed by other services

Event store implementations

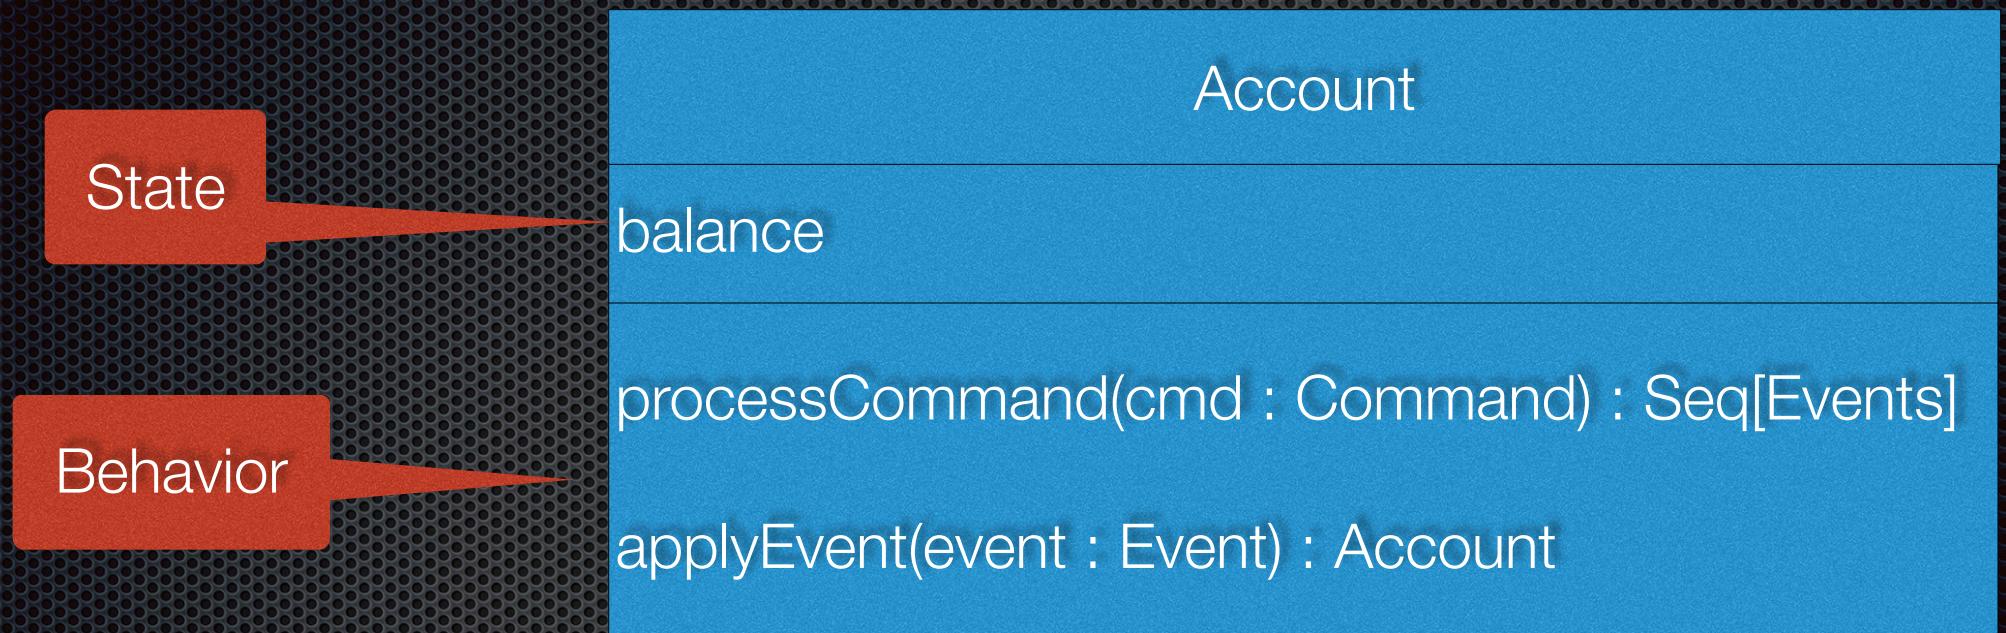

- Home-grown/DIY
- geteventstore.com by Greg Young
- My event store - <http://bit.ly/trialeventuate>

Optimizing using snapshots

- Most aggregates have relatively few events
- BUT consider a 10-year old Account ⇒ many transactions
- Therefore, use snapshots:
 - Periodically save snapshot of aggregate state
 - Typically serialize a memento of the aggregate
 - Load latest snapshot + subsequent events

Hybrid OO/Functional style example aggregate

OO = State + Behavior

Aggregate traits

Used by Event Store
to reconstitute
aggregate

Apply event returning
updated Aggregate

```
trait Aggregate[T] { self : T =>
  def applyEvent(event : Event) : T
}

trait CommandProcessingAggregate[T, -CT] extends Aggregate[T] { self : T =>
  def processCommand(command : CT) : Seq[Event]
}
```

Map Command to Events

Account - command processing

```
case class Account(balance : BigDecimal)
extends PatternMatchingCommandProcessingAggregate[Account, AccountCommand] {

def this() = this(null)

def processCommand = {
  case OpenAccountCommand(initialBalance) =>
    Seq(AccountOpenedEvent(initialBalance))

  case CreditAccountCommand(amount, transactionId) =>
    Seq(AccountCreditedEvent(amount, transactionId))

  case DebitAccountCommand(amount, transactionId) if amount <= balance =>
    Seq(AccountDebitedEvent(amount, transactionId))

  case DebitAccountCommand(amount, transactionId) =>
    Seq(AccountDebitFailedDueToInsufficientFundsEvent(amount, transactionId))
}
```

Prevent
overdraft

Account - applying events

Immutable

```
case class Account(balance : BigDecimal)
  extends PatternMatchingCommandProcessingAggregate[Account, AccountCommand] {

  def applyEvent = {

    case AccountOpenedEvent(initialBalance) => copy(balance = initialBalance)

    case AccountDebitedEvent(amount, _) => copy(balance = balance - amount)

    case AccountCreditedEvent(amount, _) =>
      copy(balance = balance + amount)

    case AccountDebitFailedDueToInsufficientFundsEvent(amount, _) =>
      this
  }
}
```

Event Store API

```
trait EventStore {  
  
  def save[T <: Aggregate[T] : ClassTag](events: Seq[Event], assignedId: Option[EntityId] = None)  
    : Future[EntityIdAndVersion]  
  
  def update[T <: Aggregate[T] : ClassTag](entityIdAndVersion: EntityIdAndVersion, events: Seq[Event])  
    : Future[EntityIdAndVersion]  
  
  def find[T <: Aggregate[T] : ClassTag](entityId: EntityId)  
    : Future[EntityWithMetadata[T]]  
  
  def findOptional[T <: Aggregate[T] : ClassTag](entityId: EntityId)  
    : Future[Option[EntityWithMetadata[T]]]
```

Reactive/Async API

Functional example aggregate

FP = Separation of State and Behavior

Account

balance

AccountAggregate

processCommand(Account, Command) : Seq[Events]

applyEvent(Account, Event) : Account

State

Behavior

Aggregate type classes/implicits

```
trait Aggregate[T, -EV <: Event] {  
    def newInstance() : T  
  
    def applyEvent(aggregate : T, event : EV) : T  
  
    def applyEvents(aggregate: T, events: Seq[EV]) : T =  
        events.foldLeft(aggregate)(applyEvent)  
}
```

```
trait Command  
  
trait AggregateCommandProcessor[T , -CT <: Command, EV <: Event] {  
  
    def processCommand(aggregate : T, command : CT) : Seq[EV]  
}
```

Functional-style MoneyTransfer Aggregate

State

Behavior

```
case class TransferDetails(fromAccountId : EntityId, toAccountId : EntityId, amount : Money)

case class MoneyTransfer(state : TransferStates.State, details : TransferDetails)

implicit object MoneyTransferAggregate extends Aggregate[MoneyTransfer, MoneyTransferEvent]
  with AggregateCommandProcessor[MoneyTransfer, MoneyTransferCommand, MoneyTransferEvent] {

  override def newInstance() = MoneyTransfer(TransferStates.NEW, null)

  override def processCommand(mt: MoneyTransfer, command: MoneyTransferCommand): Seq[MoneyTransferEvent] =
    command match {...}

  override def applyEvent(mt: MoneyTransfer, event: MoneyTransferEvent): MoneyTransfer =
    event match {...}}
```

FP-style event store

Enables inference of T, and EV

```
trait EventStore {  
  
  def save[T, EV <: Event](clasz : Class[T], events: Seq[EV], assignedId: Option[EntityId] = None)  
    (implicit ag : Aggregate[T, EV]) : Future[EntityIdAndVersion]  
  
  def update[T, EV <: Event](clasz : Class[T], entityIdAndVersion: EntityIdAndVersion, events: Seq[EV])  
    (implicit ag : Aggregate[T, EV]) : Future[EntityIdAndVersion]  
  
  def find[T, EV <: Event](clasz : Class[T], entityId: EntityId)  
    (implicit ag : Aggregate[T, EV]): Future[EntityWithMetadata[T, EV]]  
  
  def findOptional[T, EV <: Event](clasz : Class[T], entityId: EntityId)  
    (implicit ag : Aggregate[T, EV]): Future[Option[EntityWithMetadata[T, EV]]]  
}
```

Tells ES how to instantiate
aggregate and apply events

Business benefits of event sourcing

- Built-in, reliable audit log
- Enables temporal queries
- Publishes events needed by big data/predictive analytics etc.
- Preserved history ⇒ More easily implement future requirements

Technical benefits of event sourcing

- Solves data consistency issues in a Microservice/NoSQL-based architecture:
 - Atomically save and publish events
 - Event subscribers update other aggregates ensuring eventual consistency
 - Event subscribers update materialized views in SQL and NoSQL databases (more on that later)
- Eliminates O/R mapping problem

Drawbacks of event sourcing

- ❖ Weird and unfamiliar
- ❖ Events = a historical record of your bad design decisions
- ❖ Handling duplicate events can be tricky
- ❖ Application must handle eventually consistent data
- ❖ Event store only directly supports PK-based lookup (more on that later)

Agenda

- Why build event-driven microservices?
- Overview of event sourcing
- Designing microservices with event sourcing
- Implementing queries in an event sourced application

Use the familiar building blocks of DDD

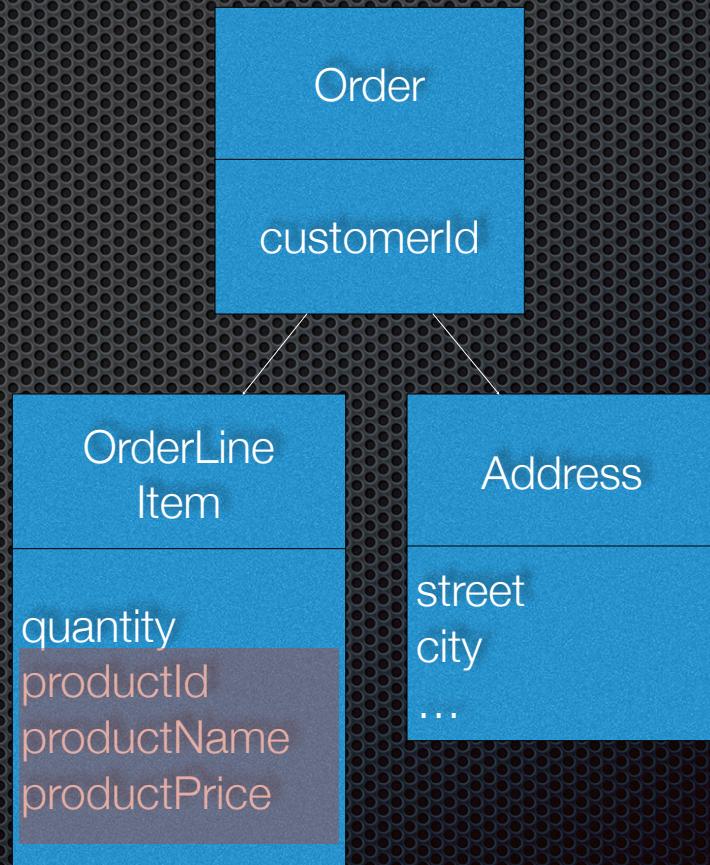

- Entity
- Value object
- Services
- Repositories
- Aggregates

With some
differences

Partition a
bounded context's
domain model
into Aggregates

Aggregate design

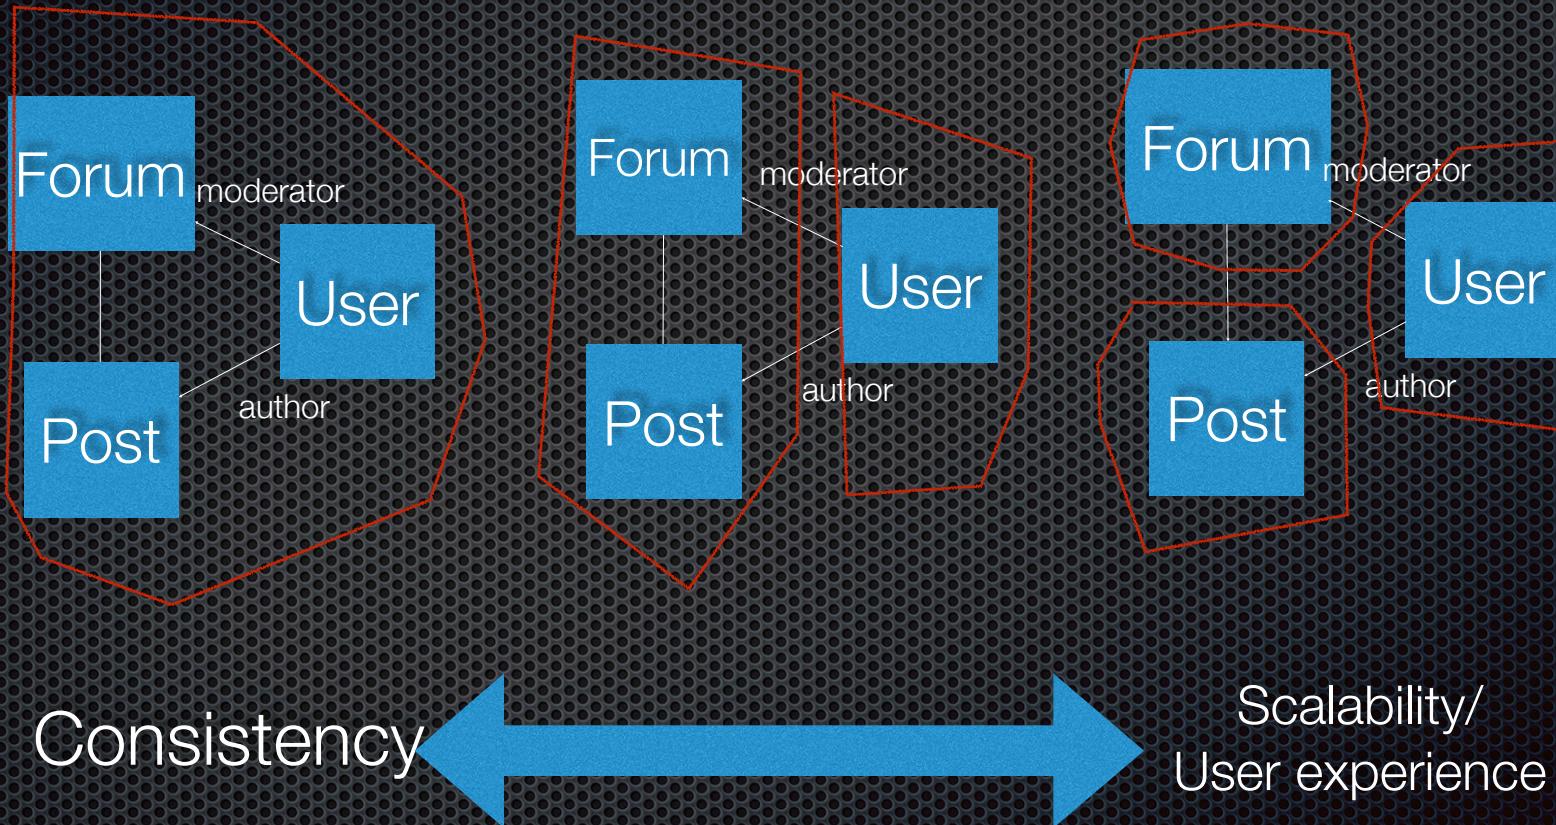

- Graph consisting of a root entity and one or more other entities and value objects
- Each core business entity = Aggregate: e.g. customer, Account, Order, Product,
- Reference other aggregate roots via primary key
- Often contains partial copy of other aggregates' data

Aggregate granularity is important

- Transaction = processing one command by one aggregate
- No opportunity to update multiple aggregates within a transaction
- If an update must be atomic (i.e. no compensating transaction) then it must be handled by a single aggregate
 - e.g. scanning boarding pass at security checkpoint or when entering jetway

Aggregate granularity

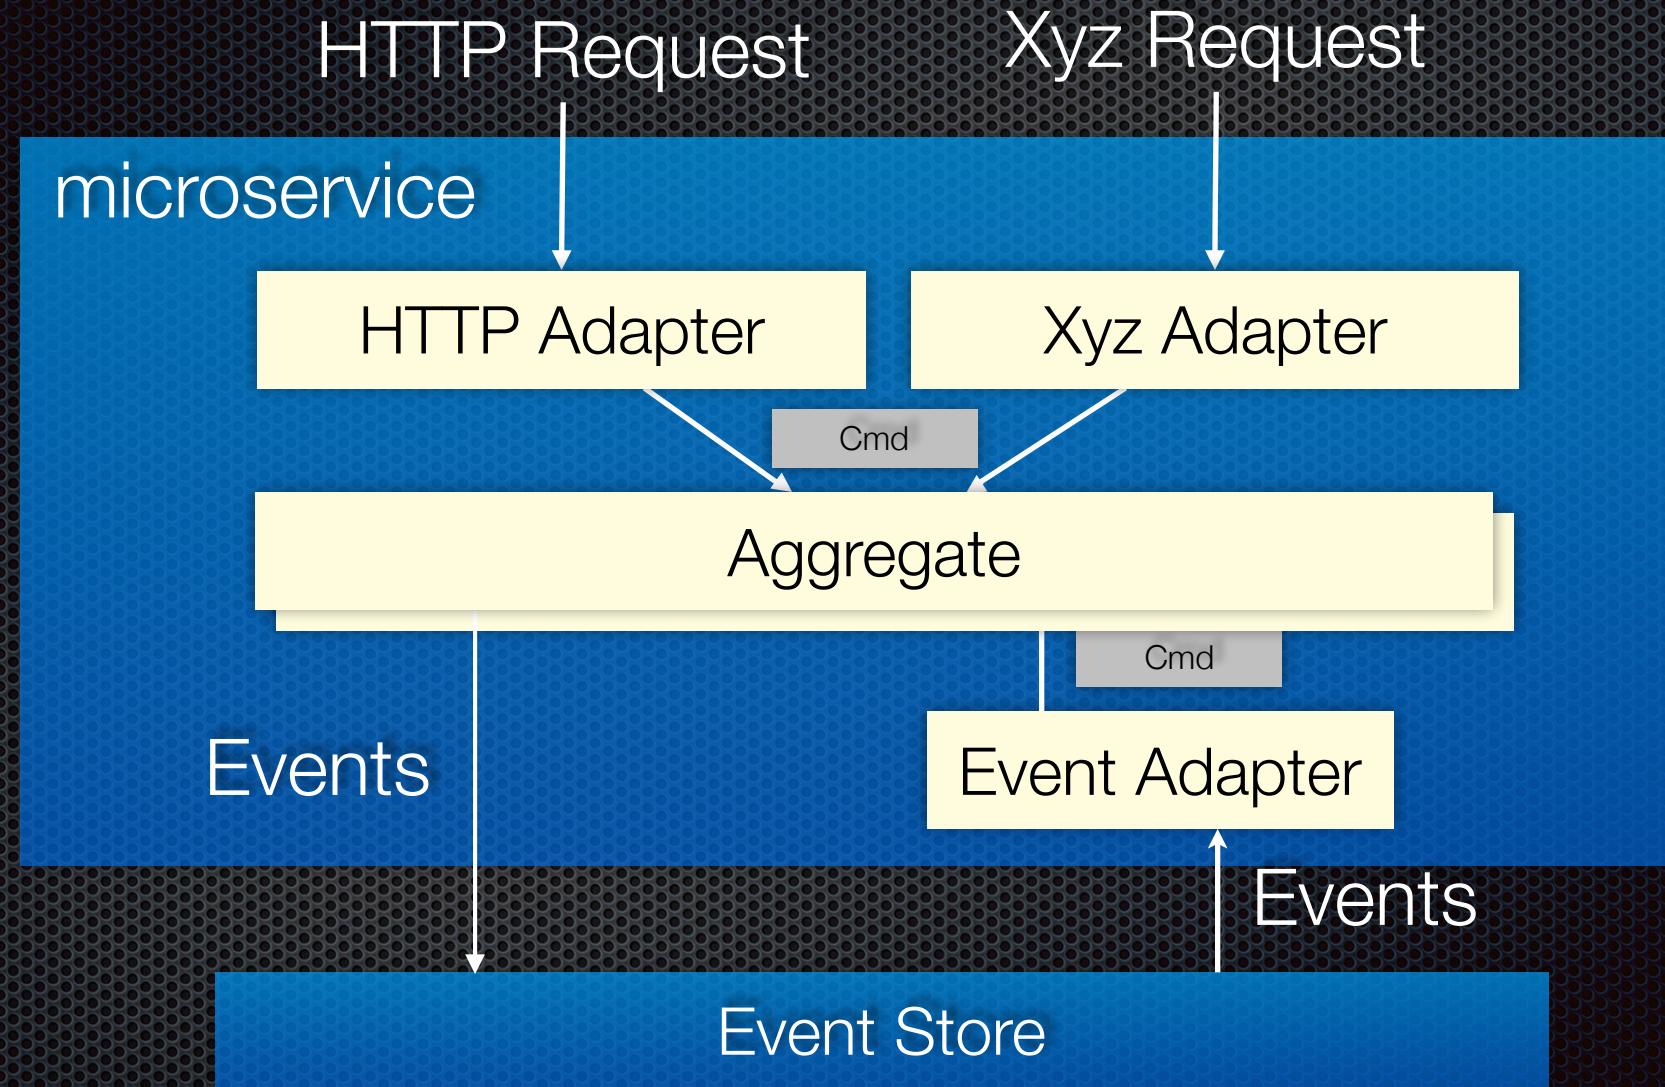

Identify the state changing
events for each Aggregate

Designing domain events

- Naming
 - Past tense to reflect that something occurred
 - Ideally specific: AccountOpened/Debited/Credited
 - Sometimes vague: FooUpdated
- Event attributes
 - Id - TimeUUID
 - Other attributes - from command, required to persist entity
- Event enrichment
 - ProductAddedToCart(**productId**) vs. ProductAddedCart(**productInfo**)
 - Extra data to support event consumers

The anatomy of a microservice

Asynchronous Spring MVC controller

```
@RestController
class MoneyTransferController @Autowired()(moneyTransferService : MoneyTransferService,
                                             eventStore : EventStore) {

  @RequestMapping(value=Array("/transfers"), method = Array(RequestMethod.POST))
  def create(@RequestBody transferDetails : TransferDetails) = WebUtil.toDeferredResult {
    for (transaction <- moneyTransferService.transferMoney(transferDetails))
      yield CreateMoneyTransferResponse(transaction.entityId.id)
  }
}
```

Scala Future => Spring MVC DeferredResult

MoneyTransferService

```
class MoneyTransferService(implicit eventStore : EventStore) {  
  
  def transferMoney(transferDetails : TransferDetails) =  
    newEntity[MoneyTransfer] <== CreateMoneyTransferCommand(transferDetails)  
}
```

DSL concisely specifies:

1. Creates MoneyTransfer aggregate
2. Processes command
3. Applies events
4. Persists events

Handling events published by Accounts

```
@EventSubscriber (id = "transactionEventHandlers")
class MoneyTransferEventHandlers(implicit eventStore: EventStore)
  extends CompoundEventHandler {

  val recordDebit =
    handlerForEvent[AccountDebitedEvent] { de =>
      existingEntity[MoneyTransfer](de.event.transactionId) <=-
        RecordDebitCommand(de.entityId)
    }
}
```

- 1.Load MoneyTransfer aggregate
- 2.Processes command
- 3.Applies events
- 4.Persists events

Agenda

- Why build event-driven microservices?
- Overview of event sourcing
- Designing microservices with event sourcing
- Implementing queries in an event sourced application

Let's imagine that you want to display an account and its recent transactions...

Displaying balance + recent credits and debits

- We need to do a “join: between the Account and the corresponding MoneyTransfers
- (Assuming Debit/Credit events don’t include other account, ...)

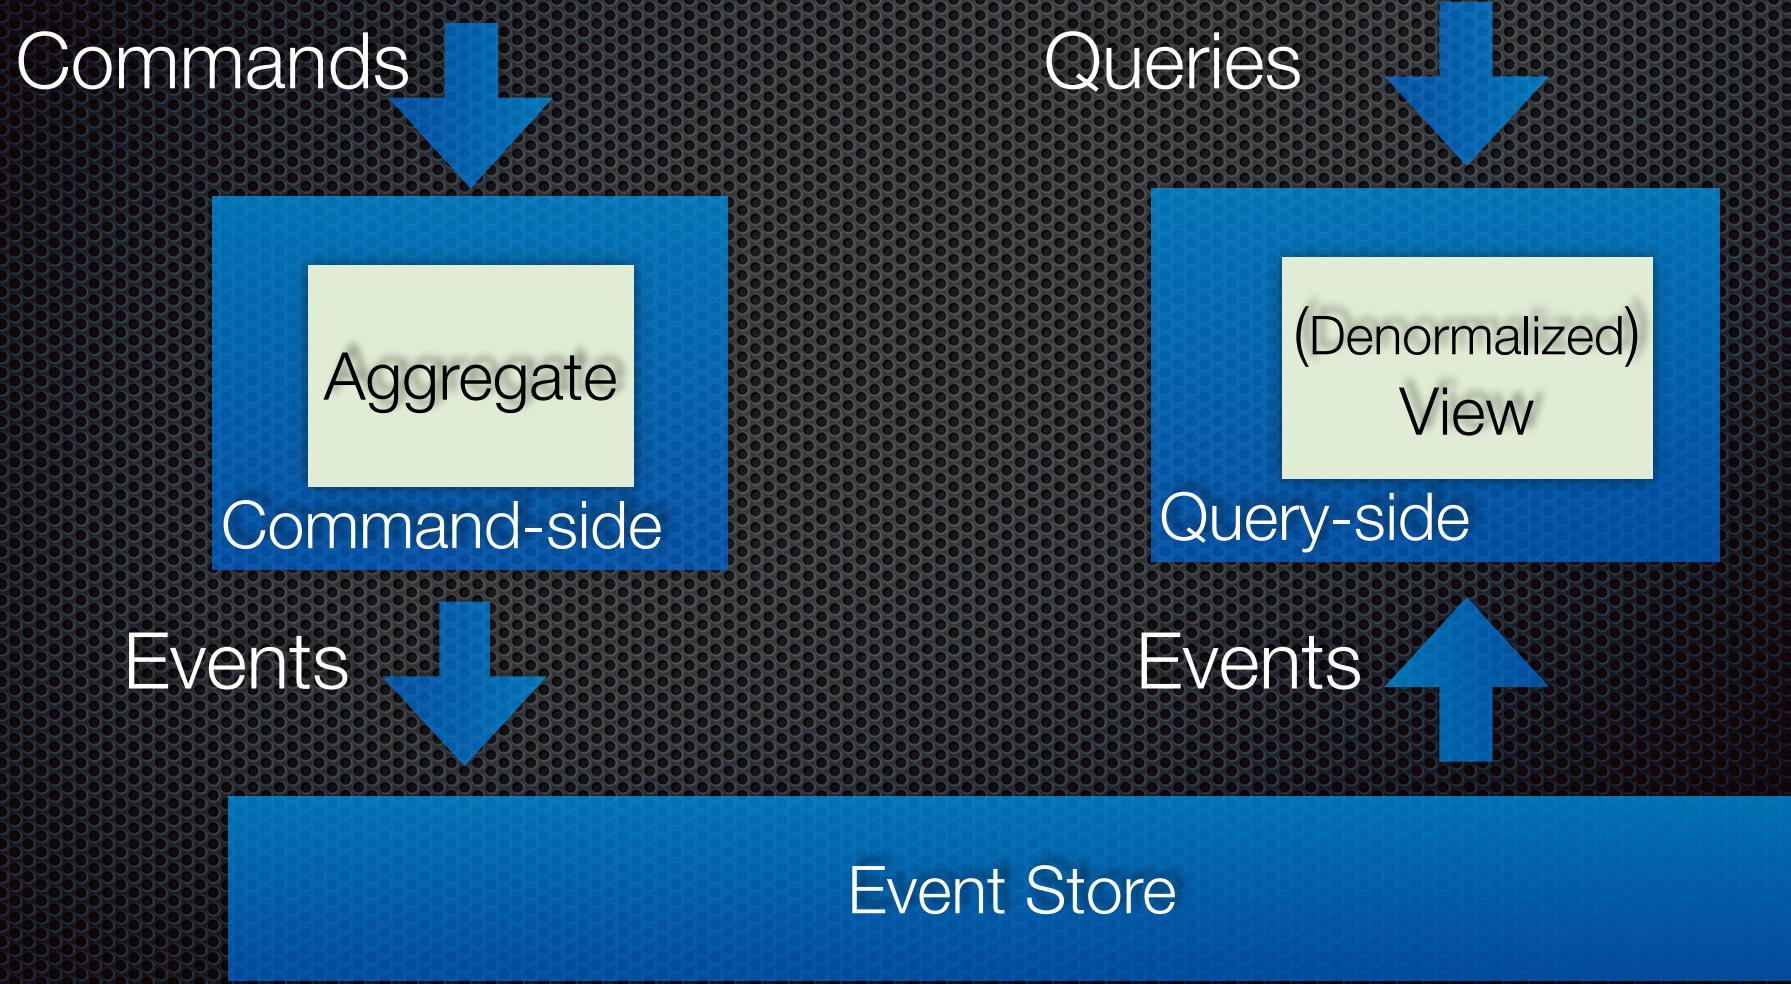

BUT

- Event Store = primary key lookup of individual aggregates, ...

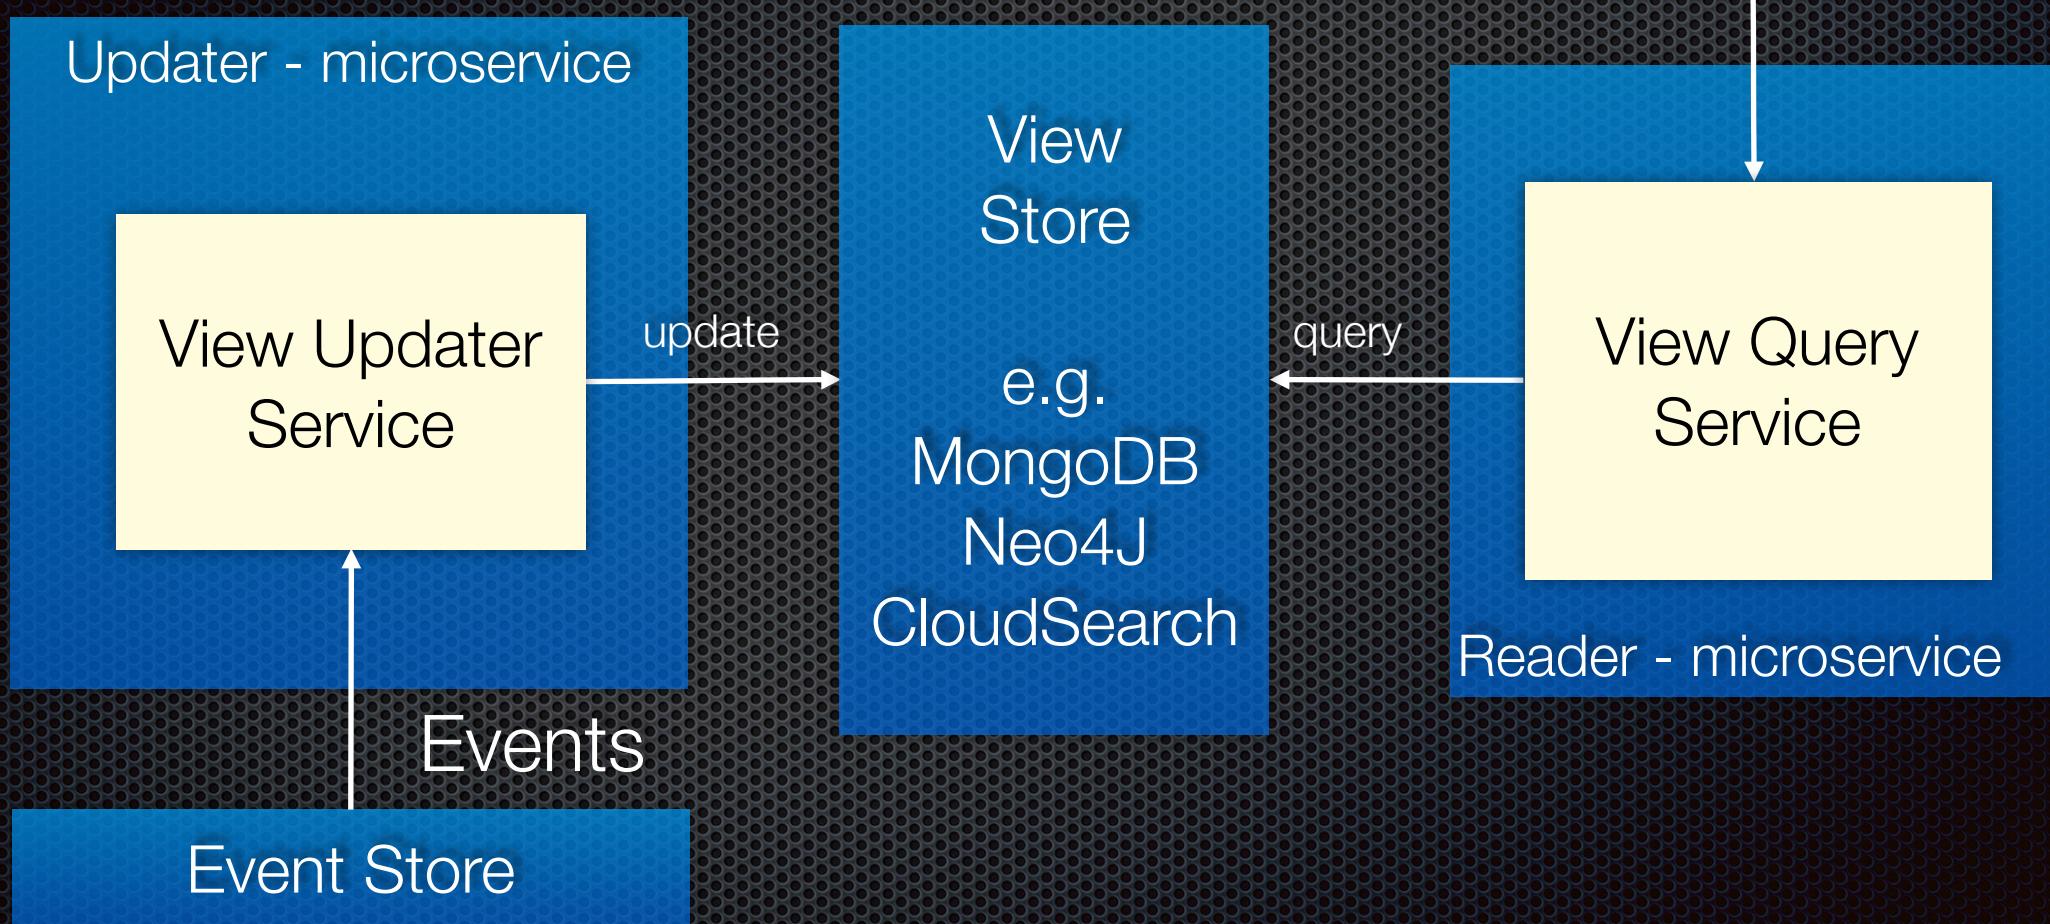

- Use **C**ommand **Q**uery **R**esponsibility **S**egregation

Command Query Responsibility Segregation (CQRS)

Query-side microservices

Persisting account balance and recent transactions in MongoDB

```
{  
  id: "298993498",  
  balance: 100000,  
  transfers : [  
    {"transferId" : "4552840948484",  
     "fromAccountId" : 298993498,  
     "toAccountId" : 3483948934,  
     "amount" : 5000}, ...  
  ],  
  changes: [  
    {"changeId" : "93843948934",  
     "transferId" : "4552840948484",  
     "transactionType" : "AccountDebited",  
     "amount" : 5000}, ...  
  ]  
}
```

Current balance

MoneyTransfers that update the account

The debits and credits

Denormalized = efficient Lookup

@crichardson

Persisting account info using MongoDB...

```
class AccountInfoUpdateService
  (accountInfoRepository : AccountInfoRepository, mongoTemplate : MongoTemplate)
    extends CompoundEventHandler {

  @EventHandlerMethod
  def created(de: DispatchedEvent[AccountOpenedEvent]) = ...

  @EventHandlerMethod
  def recordDebit(de: DispatchedEvent[AccountDebitedEvent]) = ...

  @EventHandlerMethod
  def recordCredit(de: DispatchedEvent[AccountCreditedEvent]) = ...

  @EventHandlerMethod
  def recordTransfer(de: DispatchedEvent[MoneyTransferCreatedEvent]) = ...

}
```

Persisting account info using NodeJS and MongoDB...

```
this.handlers[accountEvents.entityTypeName][accountEvents.AccountOpenedEvent] =
  function (event, callback) {
    accountViewUpdaterService.createAccount(event, callback)
};

this.handlers[accountEvents.entityTypeName][accountEvents.AccountDebitedEvent] =
  function (event, callback) {
    accountViewUpdaterService.saveAccountChange(event, -1, callback);
};

---

exports.saveAccountChange = function(event, delta, callback) {
...
  var update = {
    $inc: { balance: amount * delta },
    $push: { changes: ci },
    $set: { version: changeId }
  };

  var options = { multi: true };

  db.AccountModel.update(conditions, update, options, callback);
};
```

Other kinds of views

- AWS Cloud Search
 - Text search as-a-Service
 - View updaters batches aggregates to index
 - View query service does text search
- AWS DynamoDB
 - NoSQL as-a-Service
 - On-demand scalable - specify desired read/write capacity
 - Document and key-value data models
 - Useful for denormalized, UI oriented views

Benefits and drawbacks of CQRS

Benefits

- Necessary in an event-sourced architecture
- Separation of concerns = simpler command and query models
- Supports multiple denormalized views
- Improved scalability and performance

Drawbacks

- Complexity
- Potential code duplication
- Replication lag/eventually consistent views

Summary

- Event sourcing solves key data consistency issues with:
 - Microservices
 - Partitioned SQL/NoSQL databases
- Apply strategic DDD to identify microservices
- Apply tactical DDD to design individual services
- Use CQRS to implement materialized views for queries
